

Efficient Batch Zero-Knowledge Arguments for Low Degree Polynomials

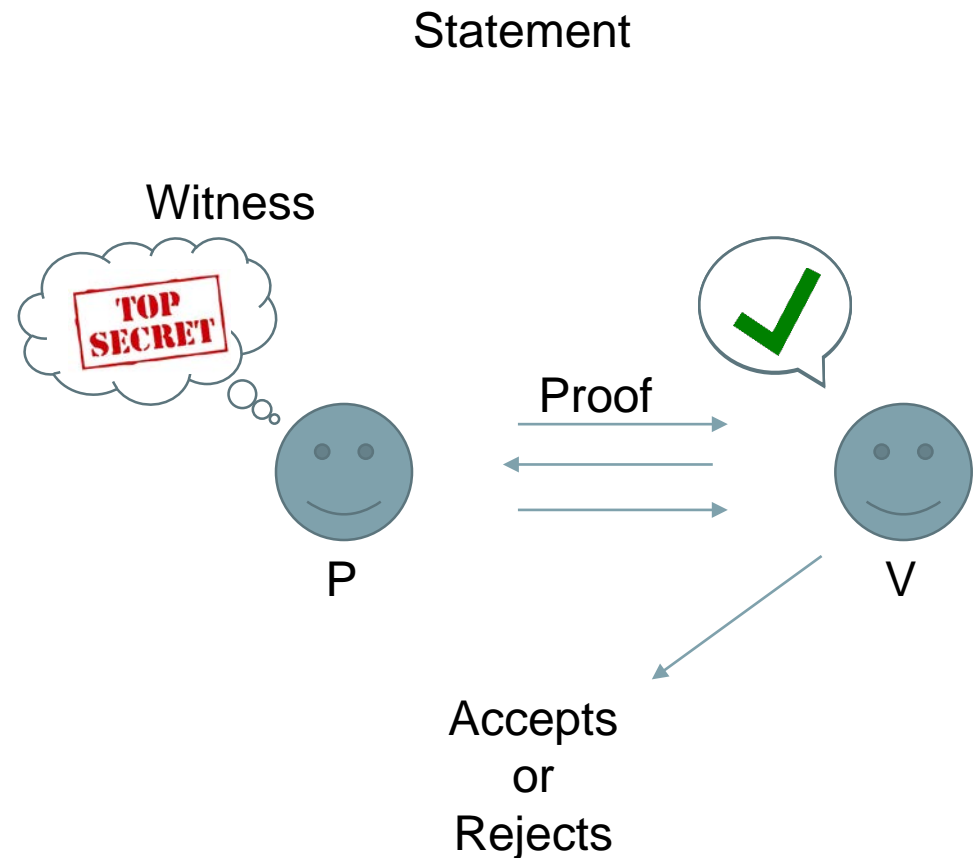

Jonathan Bootle, Jens Groth
University College London

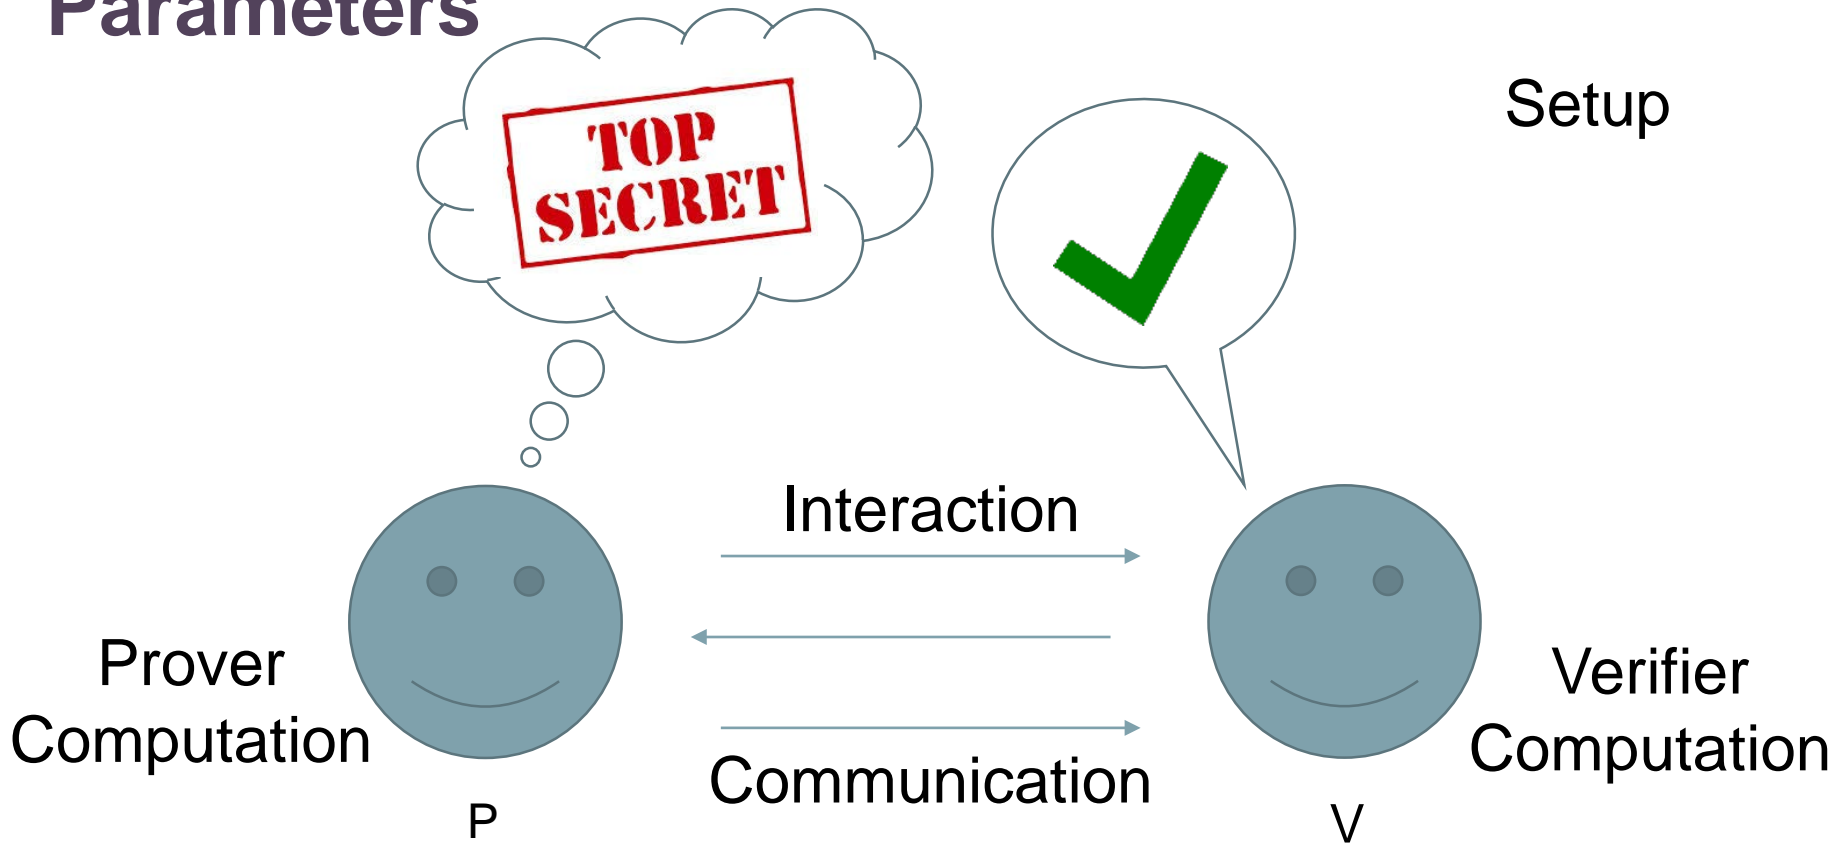

Zero Knowledge Proofs

- Completeness
- Soundness
- Zero-Knowledge

- Proof of Knowledge
- Interactive
- Public-coin

Parameters

Goal: reduce costs for special statements

This Work

$$\lambda \in \{\lambda_1, \dots, \lambda_N\}$$

- Efficient for low-depth circuits like set membership and polynomial evaluation $v = h_0 + h_1u + h_2u^2 + \dots + h_Nu^N$
- Works with homomorphic commitments
- Generalises and explains some previous works
- Avoids reductions to general statements

Applications

- Set membership proofs

$$\lambda \in \{\lambda_1, \dots, \lambda_N\}$$

- $O(\log N)$ communication, improved constants.
 -Tune to get protocol with $O(1)$ commitments

- Polynomial evaluation

$$v = h_0 + h_1u + h_2u^2 + \dots + h_nu^N$$

- $O(\log N / \log \log N)$ communication, asymptotic improvement.

Statement

- Secret witness a
- Public polynomials P and Q $P(a) = 0$
- Commitment c $c = com(Q(a); r)$

Example: committed bit

- $P(a) = a(1 - a)$
- $Q(a) = a$
- Proof that $c = com(a; r)$ and $a \in \{0,1\}$

Tweaking Statements

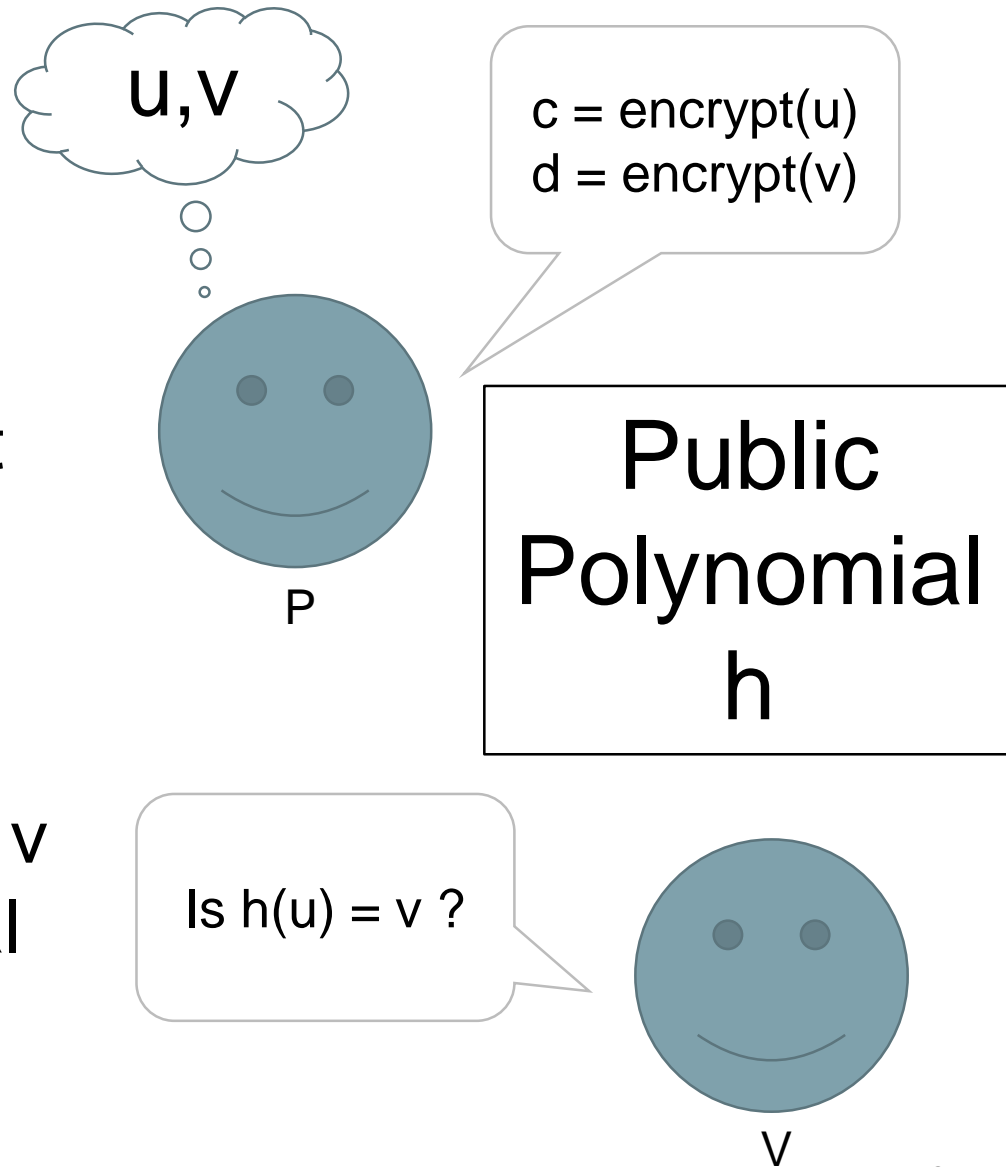

- Secret witness a
- Public tweak b
- Public polynomials P and Q
- Commitment c

$$P(a, b) = 0$$

$$c = \text{com}(Q(a, b); r)$$

Polynomial Evaluation Proofs

- The prover has secret numbers, u and v
- The prover convinces the verifier that $h(u) = v$ for a public polynomial h

Polynomial Evaluation Proofs

- $\mathbf{a} = (1, u, u^2, u^3, \dots, u^{\deg(h)})$
- $\mathbf{P}(\mathbf{a}) = a_2 \cdot (a_1, a_2, \dots, a_{\deg(h)-1}) - (a_2, \dots, a_{\deg(h)})$
- $\mathbf{b} =$ coefficients of h
- $Q(\mathbf{a}, \mathbf{b}) = \mathbf{a} \cdot \mathbf{b} = h(u)$

Batch Proofs

- Secret witnesses $a_{1,1}, \dots, a_{m,n}$
- Public tweak b
- Public polynomials P and Q
- Commitments c_1, \dots, c_m

$$P(a_{i,j}, b) = 0 \text{ for all } i, j$$

For all i , $c_i = \text{com}(Q(a_{i,1}, b), \dots, Q(a_{i,n}, b); r_i)$

t instances $\rightarrow \sqrt{t}$ communication overhead

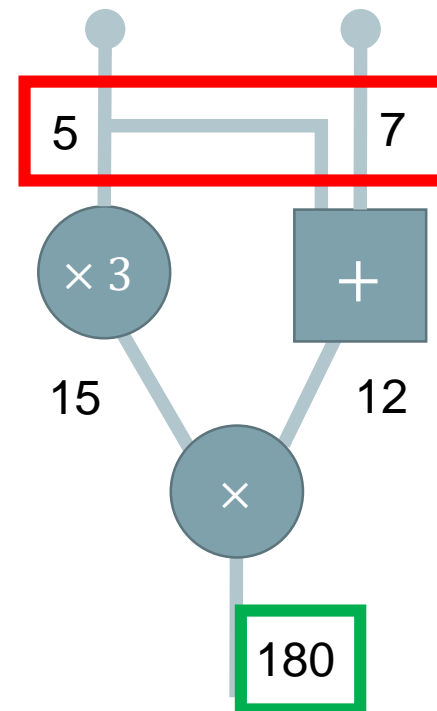

Polynomial Evaluation Proofs

Previous work	Proof Size	Year
Brands et al	$O(\sqrt{N})$	2007
Bayer, Groth	$O(\log N)$	2013
This Work	$\frac{5 \log N}{\log \log N}$	2018

N = degree of polynomial

Arithmetic Circuits

- N multiplication gates
- Prover knows inputs
- Publicly known outputs
- Check inputs give the correct outputs

General Arithmetic Circuit Proofs

Previous work	Proof Size	Year
Cramer, Damgård	$O(N)$	1997
Groth	$O(\sqrt{N})$	2009
BCCGP	$6 \log N$	2016
Bulletproofs	$2 \log N$	2017

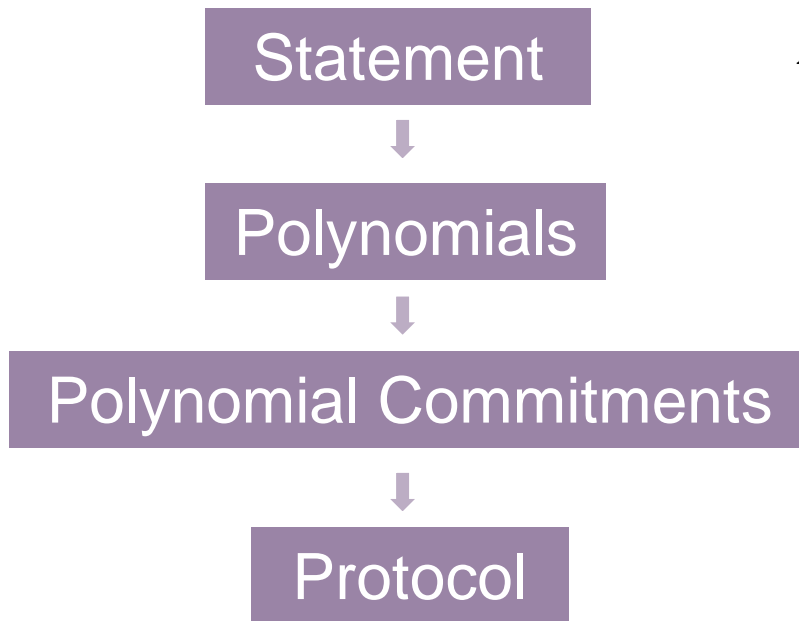

N = degree of polynomial

Is this always the best possible?

General Arithmetic Circuit Proofs

Previous work	Proof Size	Year
Cramer, Damgård	$6N$	1997
Groth	$6\sqrt{N}$	2009
BCCGP	$6 \log N$	2016
Bulletproofs	$2 \log N$	2017
This Work	$\frac{5 \log N}{\log \log N}$	2018

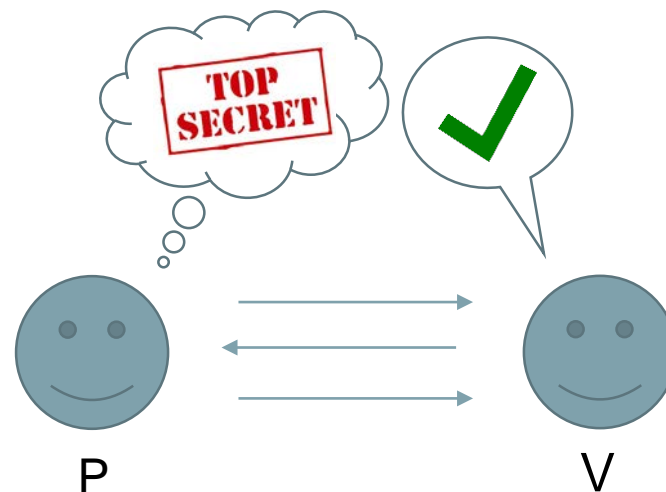

Overview

$$P(\mathbf{a}, \mathbf{b}) = 0, c = \text{com}(Q(\mathbf{a}, \mathbf{b}); r)$$

$$P(\mathbf{ax} + \mathbf{a}', \mathbf{b}) = \sum_i p_i^{x^i}$$

PolyCommit, PolyEval, PolyVerify

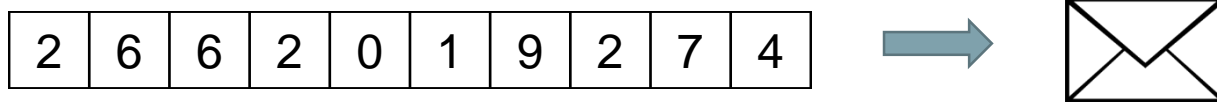

Commitments

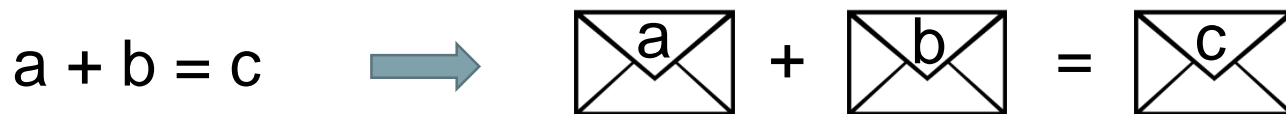

Pedersen Commitments

- Compressing

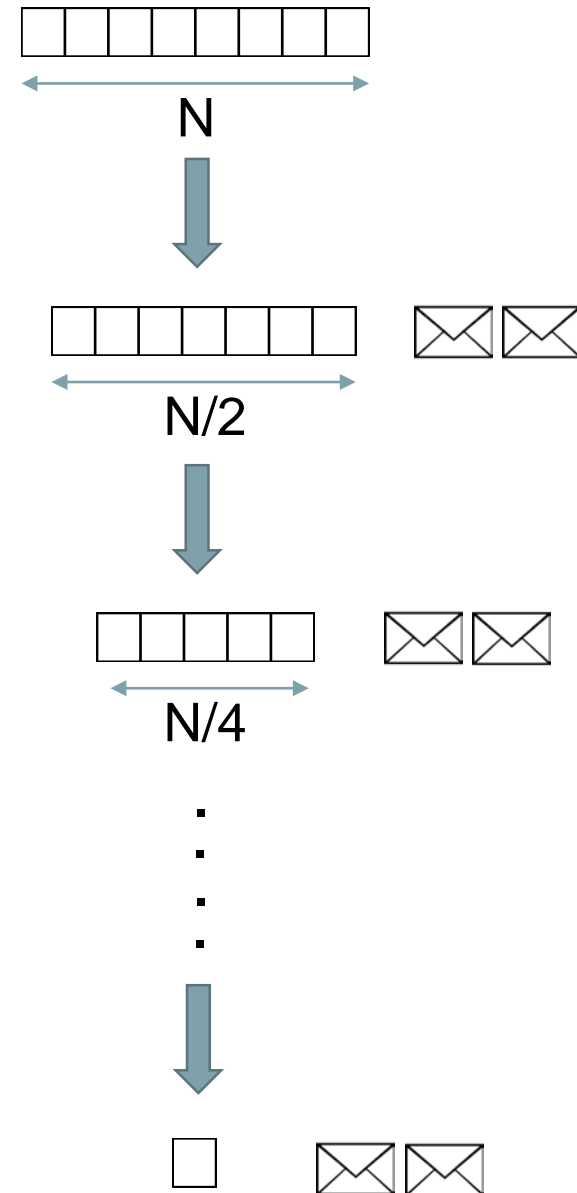

- Homomorphic

- $C = com(m_1, \dots, m_k; r) = g_1^{m_1} g_2^{m_2} \dots g_k^{m_k} h^r$
- g_1, g_2, \dots, g_k, h random elements of G

Previous Arguments

- Reduce AC-SAT to a scalar-product check
- Compress vectors of length N
- $O(\log N)$ communication costs

This Work

$$\mathbf{a} = (1, u, u^2, u^3, \dots, u^{\deg(h)})$$

$$P(\mathbf{a}) = a_2 \cdot (a_1, a_2, \dots, a_{\deg(h)-1}) - (a_2, \dots, a_{\deg(h)})$$

- Works directly with circuits
- Degree and number of inputs determines performance
- Competitive performance for circuits of degree $O(\log N)$ and $O(\log N)$ inputs, but $O(N)$ gates

Proof of Knowledge

$$c = \text{com}(a; r)$$

$$P(a) = 0$$

$$Q(a) = a$$

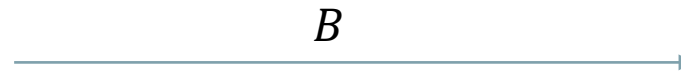

P

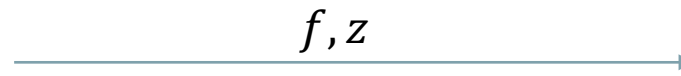

V

Choose random $a', s \in \mathbb{Z}_p$
 Compute $B = \text{com}(a'; s)$

$$f = ax + a'$$

$$z = rx + s$$

Choose random $x \in \mathbb{Z}_p$

Check that
 $\text{com}(f; z) = C^x B$

Committed Bits

- A bit a satisfies $a(1 - a) = 0$
- Prover sends $f = ax + a'$ to the verifier
- Embed $a(1 - a)$ into some polynomial
- $f(x - f) = a(1 - a)x^2 + k_1x + k_2$ for some constants k_1, k_2
- The prover commits to k_1, k_2 beforehand and shows that $f(x - f)$ is actually a polynomial of degree 1

Committed Bits Protocol

$$a \in \{0,1\} \quad P(a) = a(1 - a)$$

$$c = \text{com}(a; r) \quad Q(a) = a$$

- Commit to a'
- $f = aX + a'$

- $P(f) = k_1X + k_2$

Compute $K_1 = \text{com}(k_1; t_1)$

Compute $K_2 = \text{com}(k_2; t_2)$

commitments 

x

Choose random $x \in \mathbb{Z}_p$

f, z, v

$$f = ax + a'$$

$$z = rx + s$$

$$v = t_1x + t_2$$

Check that

$$\text{com}(f; z) = C^x B$$

$$\text{com}(f(x - f); v) = K_1^x K_2$$

Committed Bits Protocol

$$a \in \{0,1\} \quad P(a) = a(1 - a)$$

$$c = \text{com}(a; r) \quad Q(a) = a$$

Commit to random values to hide witness

Compute coefficients of a polynomial. Commit to them.

Send witness, which is hidden by adding random values.

commitments 

x

f, z, v

Choose random $x \in \mathbb{Z}_p$

Check witness.
Check polynomial has degree 1, not 2.

General Recipe

- Commit to secret vector \mathbf{a} and random vector \mathbf{a}'
- Prover sends $\mathbf{f} = \mathbf{a}x + \mathbf{a}'$ to the verifier
- If $P(\mathbf{a}) = \mathbf{0}$, then $P(\mathbf{f})$ has a zero in the leading x coefficient
- Commit to other coefficients in advance

General Recipe

- $P(\mathbf{f}, \mathbf{b}) = P(\mathbf{a}, \mathbf{b}) + \sum_i \mathbf{p}_i x^i$
- Make commitments $P_i = \text{com}(\mathbf{p}_i)$
- Check $\text{com}(P(\mathbf{f}, \mathbf{b}); v) = c \cdot \prod_i P_i^{x^i}$
- Improve efficiency using polynomial commitment protocol
- Also want to
- $Q(\mathbf{f}, \mathbf{b}) = Q(\mathbf{a}, \mathbf{b}) + \sum_i \mathbf{q}_i x^i$
- Make commitments $Q_i = \text{com}(\mathbf{q}_i)$
- Check $\text{com}(Q(\mathbf{f}, \mathbf{b}); v) = c \cdot \prod_i Q_i^{x^i}$

General Protocol

$$P(a, b) = 0$$

$$c = \text{com}(Q(a, b); r)$$

Commit to random values to hide witness

Compute coefficients of a polynomial. Commit to them. **PolyCommit**

commitments 

x

Choose random $x \in \mathbb{Z}_p$

Send witness, which is hidden by adding random values. **PolyEval**

f, z, v

Tuneable parameters

Check witness. Check polynomials. **PolyVerify**

PolyVerify

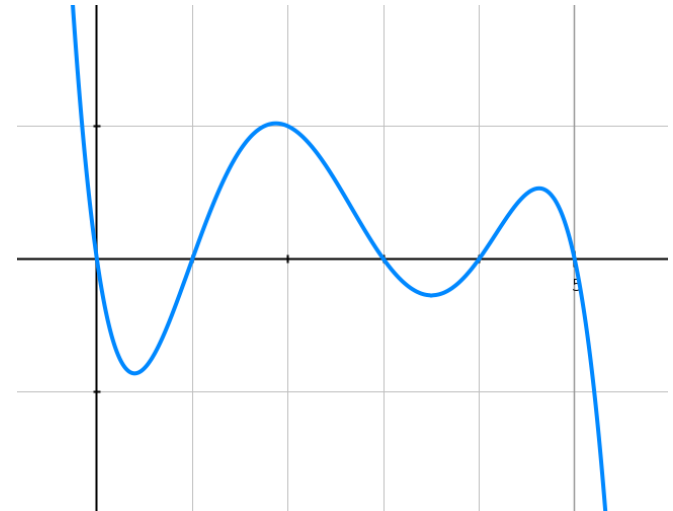

Batch Protocol Idea

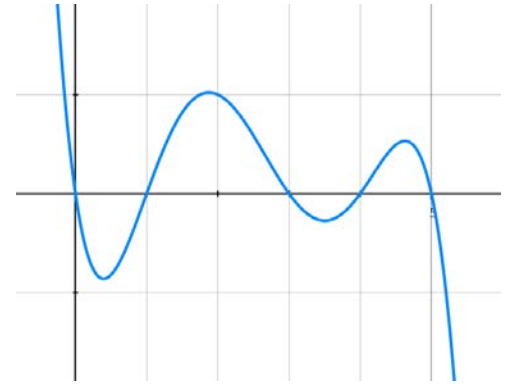

- Verify many instances of the same relation in parallel using interpolation
- Evaluate polynomials on single elements

Lagrange Polynomials

- Interpolation points z_1, \dots, z_n
- $l_i(X) = \prod_{j \neq i} \frac{X - z_j}{z_i - z_j}$ for $1 \leq i \leq n$
- $l_i(z_j) = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{otherwise} \end{cases}$
- Set $l_0(X) = \prod_i (X - z_j)$

Batched Protocol

- Secret vectors $\mathbf{a}_{1,1}, \dots, \mathbf{a}_{m,n}$
- Prover sends $\mathbf{f}_i = \sum_j \mathbf{a}_{i,j} l_j(x) + \mathbf{a}' l_0(x)$ to the verifier
- If $P(\mathbf{a}_{i,j}) = 0$, then $P(\mathbf{f}_i) = 0 \text{ mod } l_0(x)$
- Use polynomial commitment

Advantages over General Circuit Protocols

- Same or better communication complexity for low-depth circuits
- $O(N) \rightarrow O(\log N)$ cryptographic operations
- $O(\log N) \rightarrow 3$ round protocols
- No special properties needed e.g. key homomorphic commitments

Thanks!
